Outline

1 Introduction and Background

2 Methods

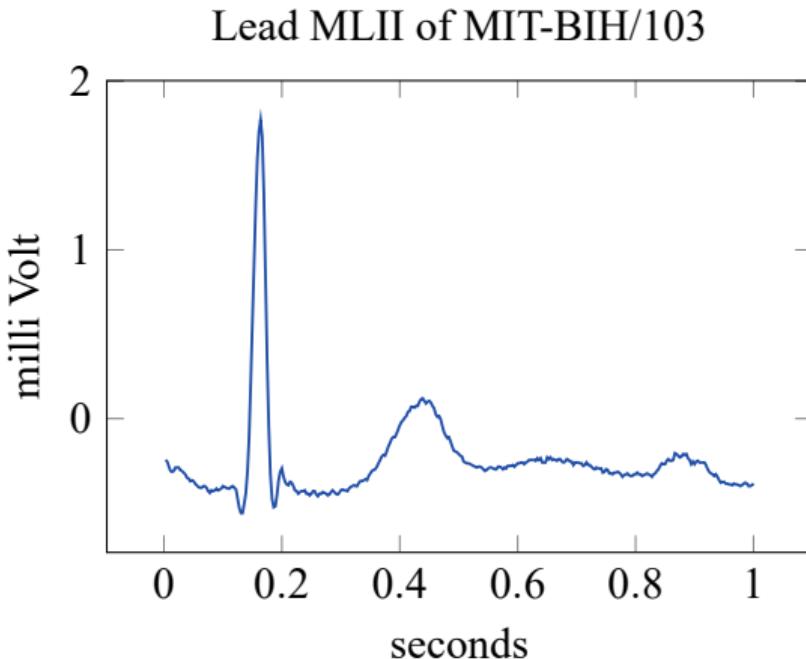

3 Results

4 Conclusion

Introduction

- ischemic heart disease (IHD) makes up 16% of global deaths but can be diagnosed using an electrocardiogram (ECG or EKG)
- manual ECG analysis is slow and error-prone, computers can help
- long ECGs are problematic even for computers → simplification through representation
- such representations should be simple, but still correspond to the original data

What is an ECG?

- records the heart's electrical activity
- contains up to 12 leads (simultaneous measurements)

Figure 1: ECG of one heartbeat.

Representation and Classification

- for simplification, time series can be represented, e.g. as SAX or MSAX
- then, the representation can be analyzed instead of the raw data
- HOT SAX can be used to classify ECG segments into discord and non-discord
- this work uses HOT MSAX to combine MSAX and HOT SAX

Research Questions & Hypothesis

- effectiveness of the methods will be judged by recall and precision
- using the MIT-BIH ECG database, determine the parameters maximizing HOT SAX and HOT MSAX recall
- compare recall value for best parameters
- HOT MSAX should have higher recall than HOT SAX if both use their best parameters

Method Background

- Lin *et al.* (2003):
Symbolic Aggregate Approximation (SAX): simplified, symbolic representation
- Keogh *et al.* (2005):
Heuristically Ordered Time series using SAX (HOT SAX): discord discovery algorithm using SAX
- Anacleto *et al.* (2020):
Multivariate SAX (MSAX): expands SAX to multivariate time series

Novel Contributions

- application of MSAX to ECG discord discovery and medical data in general
- the HOT MSAX algorithm, a modification of HOT SAX that uses MSAX
- the expansion of HOT SAX to multivariate time series through HOT MSAX

SAX and MSAX – Overview

SAX		MSAX
Application		
univariate time series, e.g. a single ECG lead		multivariate time series, e.g. multiple ECG leads (whole ECG)
Steps		
(1) univariate z-normalization (2) PAA dimension reduction (w) (3) SAX discretization (a)		(1) multivariate z-normalization (2) PAA dimension reduction (w) (3) SAX discretization (a)

SAX and MSAX – Step (2)

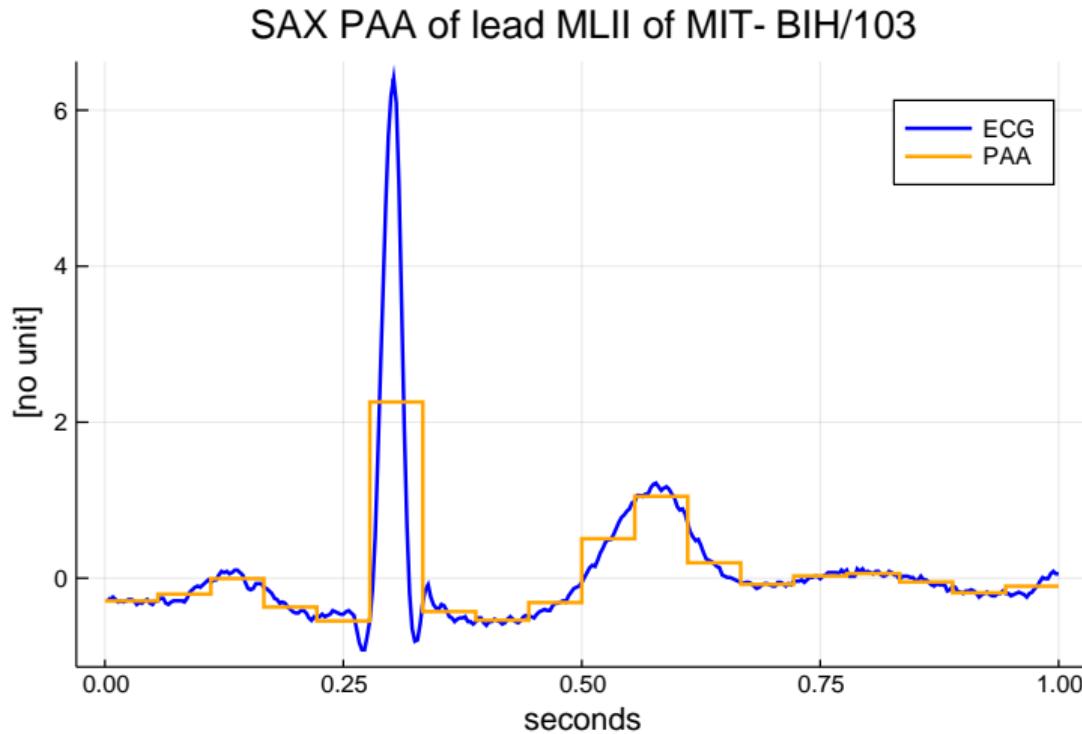

Figure 2:
ECG with
PAA, $w = 18$

SAX – Step (3)

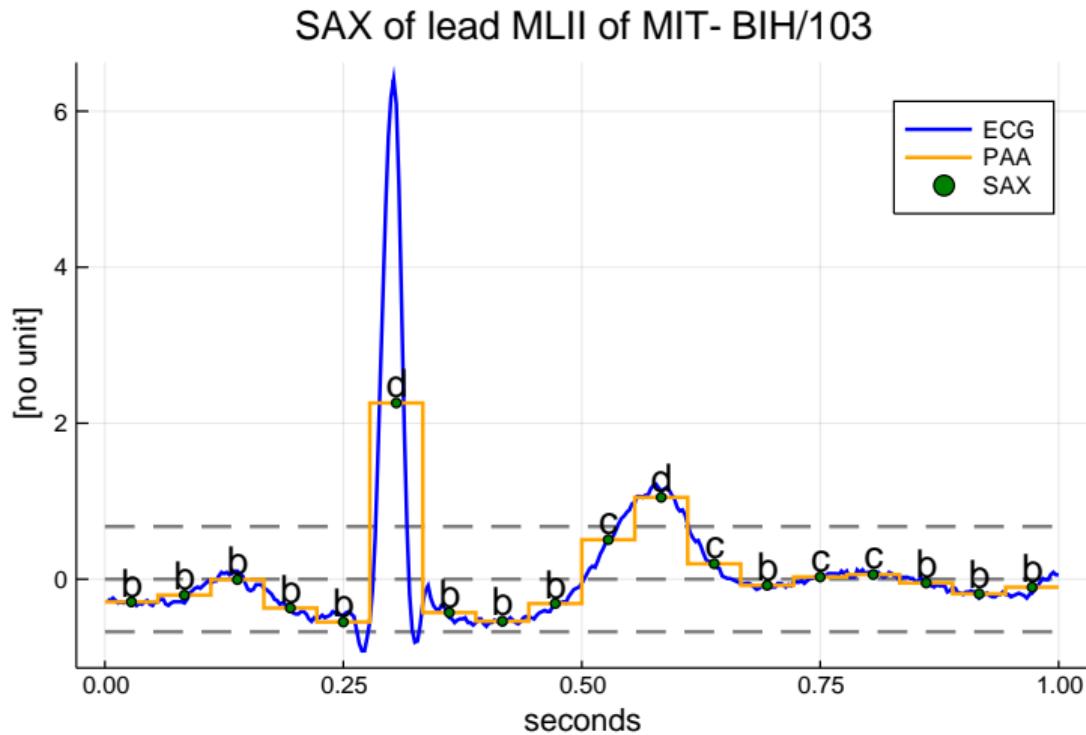

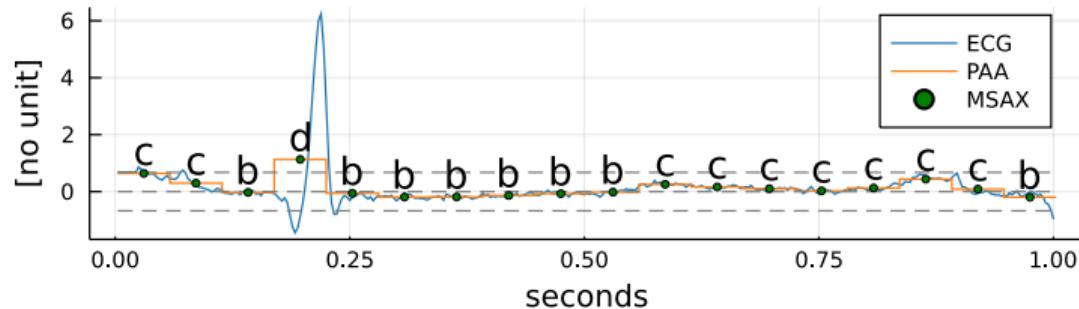

Figure 3:
ECG with
SAX, $w = 18$,
 $a = 4$)

MSAX – Step (3)

MSAX of lead MLII of MIT-BIH Database/100

MSAX of lead V5 of MIT-BIH Database/100

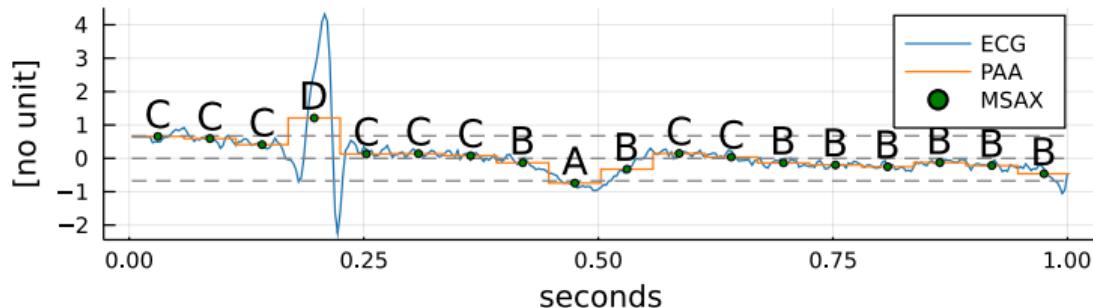

Figure 4:
ECG with
MSAX,
 $w = 18$,
 $a = 4$)

SAX and MSAX – Distance Measure

- needed to compare two SAX/MSAX segments
- sum of distances between symbols
- symbol distance is based on difference of breakpoints
- lower-bounds Euclidean Distance, i.e. corresponds to “real” distance

HOT SAX and HOT MSAX – Overview

- HOT SAX: find discords in SAX-represented time series
- speeds up the “brute force” approach
- classifies time series segments into “discord” and “non-discord”
- HOT MSAX: uses MSAX instead of SAX
- HOT MSAX can work with multivariate time series

HOT SAX and HOT MSAX – Heuristic

- two parameters: m and k
- two assumptions:
 - time series discords are rare
 - segments similar to discords may also be discords
- speed up discord discovery:
 - consider rarest segments first
 - consider segments similar to the rarest first

Analysis Process

- (1) perform HOT SAX and HOT MSAX for many parameter combinations for all ECGs in the MIT-BIH database
- (2) find recall for each combination
- (3) set recall threshold of 95%, then sort by precision
- (4) choose top 10 of those parameters for each method
- (5) choose best parameters for each method using box plot, interquartile range, outliers

Three Datasets

- (1) S-SAX: data for HOT SAX algorithm, considering each lead separately
- (2) D-SAX: data for HOT SAX, considering both leads combined
- (3) MSAX: data for the HOT MSAX algorithm

Overview of Results

Table 1: Coarse Overview of Results. Shown are sets of parameters for each method that satisfy the recall threshold of 95%.

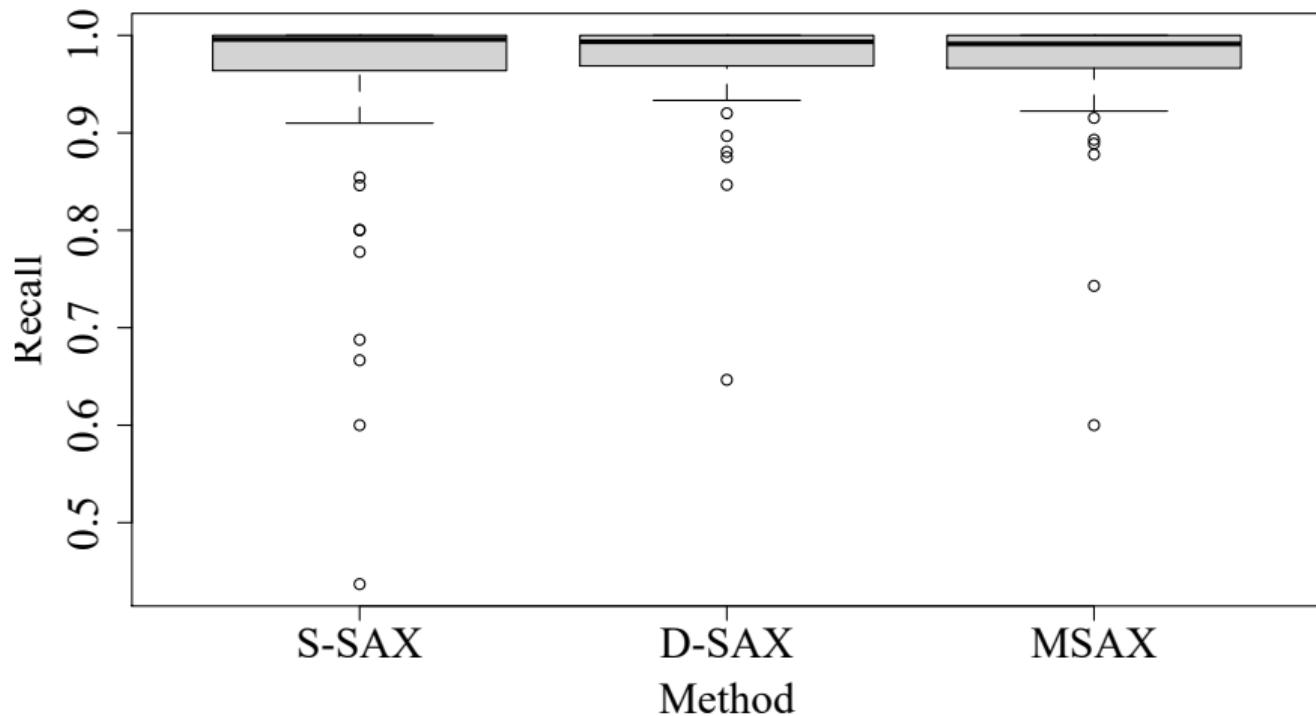

Method	Total Sets	Sets Satisfying recall $\geq 95\%$
S-SAX		99 (1.2%)
D-SAX	4,968	192 (3.9%)
MSAX		255 (5.1%)

Best Parameter Sets by Method

Table 2: Best Parameter sets for each of the methods. Best overall parameters highlighted in bold.

Method \ Parameter	k	w, m	a
S-SAX	-1	36	21
D-SAX	-1	12	24
MSAX	-1	12	17

Boxplot of Recall by Method for Optimal Parameters

Comparing Best Parameter Sets – Recall

Table 3: Statistical measures for recall of optimal parameter sets. Best overall values highlighted in bold.

Method \ Measure	IQR	Median	Outliers
S-SAX	0.035	99.60%	11
D-SAX	0.030	99.35%	6
MSAX	0.033	99.13%	6

Discussion

- no statistically significant difference in recall for the methods
 - hypothesis cannot be supported
- MSAX has both the smallest alphabet size and highest dimension reduction
 - this points to MSAX being more efficient in achieving the same results
- Anacleto, Vinga, and Carvalho [5] showed similar performance for ECG classification, supports this work's conclusion

Conclusion

- could not demonstrate superiority of HOT MSAX for best parameters
- contributed the HOT MSAX method to literature
- HOT MSAX was found to be more efficient than HOT SAX
- showed viability of a discord classifier for ECG analysis
